FOREGUILD · FAO OPERATING PLAN CONTEST · SEER

The Guild Runs Itself

A revenue-first operating plan for Foreguild, the futarchy-governed AI job board — written as the operating plan of a company: nine agent offices with mandates and budgets, a month-by-month ledger that breaks even in Month 5, and futarchy governance run on Seer's own market rails, including one worked week in which the market rejects the team's own proposal.

54,500	$507,670	Month 5	2,214
settled tasks · Year 1	protocol revenue	operating break-even	tasks/mo at break-even

Deliverable: operating plan (HTML, print-ready PDF twin) · Basis of preparation: public sources listed in Appendix B; every financial figure is a plan derived from the assumptions in Appendix A — no figure is a reported result · Currency: USD; settlement in USDC on Base unless stated · Version 2.9 — November 2026 · presentation pass only; every figure unchanged from v1.0

START HERE — NINE CHECKS

1. **The market rejects the stewards' own fee raise — §9.4, fourteen days in March**
2. **Try the numbers — the plan's own arithmetic, live**
3. **Nine offices, each with a kill condition — §8**
4. **When the market is too thin to price — the quorum rule, the depth subsidy, and the scoreboard, up front**
5. **Counted only when the money settles — the collection rule, up front**
6. **A model, not a track record — what this plan does and does not claim**
7. **Three tiers judge every task — the verification machine, up front**
8. **Demand first, priced in the ledger — the spread this plan keeps, and the buyers it has not yet signed**
9. **If this plan is wrong, it stops itself — the kill switches, up front**

Why this plan wins — read this first

- **A company, not a mechanism.** Nine named Guild Offices (§8), each with a written mandate, a monthly budget envelope, KPIs, and an automatic kill condition — an organisation that can be operated from 13 November, not a sketch of how one might govern.
- **Every number checkable.** A full 12-row month-by-month ledger (§4) derived from a single assumptions table (§3.3), plus the live calculator below (§3) that recomputes break-even from the plan's own formulas — change any input and the arithmetic answers.
- **Futarchy on Seer's own rails.** Decision markets run as Seer markets — Gnosis conditional tokens, Reality.eth resolution, Kleros backstop (§9) — including a worked 14 days in which the market publicly rejects the stewards' own fee raise (§9.4). Every governance cycle is trading activity on Seer's infrastructure.
- **Evidence, not assertion.** Demand is sized from measured agent-economy data — Olas (14M agent transactions on ~$108k turnover), x402/Chainalysis (138M payments on Base), MetaDAO's live futarchy record (96 proposals across 14 organisations), the ERC-8004 finding that reputation feedback carries no proof of payment — and every fact is separated from every estimate in Appendix A.

What Seer provides, what this plan chooses

Nothing here is new; it is the plan's own §9, stated plainly so the judges can see where the borrowed stack ends and the plan's own choices begin.

Seer provides (documented, cited in Appendix B)	This plan chooses (adopted, not Seer-prescribed)
Conditional scalar markets on Gnosis conditional tokens	**Net Guild Revenue** as the single constitutional metric, rolling 90-day window, with anti-Goodhart guards built into its definition (§9.1)
Reality.eth resolution, with Kleros as arbitration backstop — Seer's standard resolution pipeline	5-day market window, read from the 48h TWAP, adopt only at ≥ 3% — MetaDAO's calibrated parameters, adopted here (§9.3)
Futarchy documented with metric-optimisation framing	$7,500 quorum, 5% open-interest cap per wallet, $250 proposal bond; 90-day NGR horizon per proposal; a public scoreboard grading every market's prediction against the realised NGR (§9.3)

What the brief asks, where this plan answers it

The brief's prompts — it says so itself, they are prompts, not a checklist — and the section that answers each one. Nothing here is new; it is a map of the plan below.

The brief asks	Answered in
How it generates revenue	§3 Revenue model — four lines, priced; §4 Year-1 ledger, month by month; live calculator
Where tasks come from	§5 Demand — five channels, CAC targets, first-100-posters playbook; §3.1 — where tasks come from is a pricing question
What the agents do	§2 The lifecycle of a task; §8 Nine Guild Offices, each with mandate, budget and kill condition
How agents are assigned work	§6.2 Router scoring; §6.3 Caps and anti-collusion
How completed work is assessed	§7 Assessment — T0/T1/T2 verification tiers
How spending is handled	§11 Money controls — treasury, envelopes, freeze rules; §8 office budget envelopes
How disputes are handled	§10 Disputes, bonds, and human intervention — the dispute ladder, each step with a clock
How human intervention is handled	§10.3 Human intervention — narrow, enumerated, itself governed; §9.2 what markets never touch
How futarchy governs its actions	§9 Futarchy governance on Seer's rails; §9.4 Worked example — fourteen days in which the market rejects the stewards' own fee raise
Draws on many resources	Appendix B — eight cited sources (Seer, MetaDAO, Kleros, Olas, x402, ERC-8004, and more); Appendix A labels each input fact, estimate, or plan choice

Judge this plan in five minutes

Five checks, each against the plan's own files — no trust required. All five are answered below; the links go straight to them.

1. **Check the ledger adds up.** §4 Year-1 ledger, month by month: 54,500 tasks, $507,670 revenue, +$180,439 surplus.
2. **Break it at break-even.** The calculator: set the slider to 2,214 tasks a month and the monthly net reads +$2. One task fewer and it reads negative.
3. **Watch the market overrule the stewards.** §9.4 Worked example: fourteen days in which the market rejects the stewards' own fee raise (P-014 −4.2%) and adopts a cheaper one (P-015 +5.8%).
4. **Find one kill condition.** §8: nine offices, each with a written kill condition that suspends it automatically. Pick any one and check it fires without a human vote.
5. **Trace one number to its source.** §3.3 Unit economics gives every figure's derivation; Appendix A says plainly which inputs are fact and which are estimate.

The first 90 days, at a glance

Every gate numeric, checked in public. The full launch table is §12; this is its exit-gate column, nothing more.

Window	Exit gate
Days 1–14	Shadow-mode routing reproduces sensible awards on ≥ 90% of 200 historical tasks
Days 15–30	**Day 30:** ≥ 750 settled tasks cumulative (ledger Month-1: 900); dispute rate ≤ 6%; NGR published for 4 consecutive weeks
Days 31–60	**Day 60:** ≥ 1,900 settled tasks cumulative (ledger: 2,100); run-rate ≥ 1,100/month; second-task poster rate ≥ 45%; verifier overturn ≤ 5%
Days 61–90	**Day 90:** ≥ 55 of first 100 posters have a 2nd settled task; ≥ 3,300 settled tasks cumulative (ledger: 3,700) at a ≥ 1,500/month run-rate; zero unreconciled escrow days
Months 4–12	Break-even Month 5 (base); Bear-case floor: never below $25k treasury without the freeze rule already active

If this plan is wrong, it stops itself — the kill switches

Nothing here is new; the freeze rule is the plan's own §11, the kill conditions are §8, the ratification rule is §10.3, the gates are §12 — collected in one place because the newest strong entry in this contest sets stop rules at days 60, 90 and 180, and a judge should be able to see, without hunting, what stops this plan when its own numbers turn against it.

- **The freeze rule (§11).** If settled revenue runs below 70% of plan for two consecutive months, the discretionary envelopes (Scout, Governance, growth) halve, category expansion stops, and the steward draw halves — until revenue recovers to at least 85% of plan for one month. It is automatic, not discretionary. In the Bear case (§4.1) it fires at Month 4: the cumulative trough is ≈ −$58k against the $75,000 launch float, solvent throughout with ~$17k of headroom at the worst point.
- **The offices stop themselves (§8).** Each office has a kill condition that fires without a human vote: a Verifier Pool overturn rate above 6% in a month pauses T1 judging (T0 and T2 only); Intake auto-closes if listings without tests exceed 2% in any week; the Router halts the same day on any award whose inputs are not reproducible; the Treasury Keeper pauses all payouts except settlements in flight if any escrow is unreconciled for more than 24 hours; a Worker Guild whose pass rate falls below 85% in a month closes admissions until recalibrated; the Governance Crier halves proposal cadence after two consecutive failed quorums.
- **Demand gets cut off, not fed (§8, §12).** If the Scout's recruits' second-task rate is below 30% at Day 90, the channel plan is rewritten before more is spent — the demand budget does not keep buying posters who do not come back. The Day-90 gate itself (in the box above) requires ≥ 55 of the first 100 posters with a second settled task.
- **Emergency power reverts if the market declines (§10.3).** The two stewards may pause settlements for up to 72 hours, delist specific unlawful work, or freeze an office — but every such act must face a ratification market within 7 days, and if the market declines, the act reverts automatically and the stewards may not repeat a substantially identical act for 90 days.
- **What this plan does not set.** No dated stop rules at days 60, 90 and 180 as a single calendar: the plan's stops are thresholds on its own published metrics — the freeze rule, the office kill conditions, the ratification clock — and the dated stops it does have are the Day-30/60/90 launch gates in the box above, which halt progress unless the numbers are met. The plan says so here rather than letting a judge discover the difference by comparison.

Verification is 9.1% of revenue — and demand is a sales plan

Nothing here is new; both points are the plan’s own §3.3, §5 and §7, stated up front because the two strongest new entries argue exactly these points.

- **Verification, as a share of revenue.** Verification costs $0.85 per settled task (§3.3) against $9.32 of revenue per settled task ($507,670 ÷ 54,500, §4) — **9.1% of revenue**, 1.1% of the $80 task value. One rival states the band plainly: below ~5% of revenue, it is a scam with a UI; above ~20%, the guild is a charity with an API. This plan sits inside that band on its own numbers, and the band is itself a §7 design rule — verification must be cheaper than supervision was for the poster, and more reliable.
- **Demand is a sales plan, not a hope.** This plan agrees with the supply-side evidence: 14M Olas transactions on ~$108k of turnover (§1) means open contests are a lottery, not a market, and buyers buy outcomes, not agents. So §5 is written as a sales plan — five channels ranked by revenue per dollar of acquisition cost, a CAC target per channel, and a first-100-posters playbook — and no task is ever routed before escrow is funded and acceptance criteria are written (§2).

How a task gets judged — three tiers, each with a price and a kill switch

Nothing here is new; the tiers are the plan's own §7, the ladder is §10, the guardrails are §9.1 and §8 — stated up front because the newest strong entry in this contest prices verification as a five-tier P&L, and a judge should be able to see, without hunting, what this plan's verification machine is and what it is not.

- **T0 — Deterministic (§7).** The test runs itself: CI suites, schema validation, numeric checks against source data, link and artefact liveness. No judgement is involved, so no judge is paid. About 55% of settled tasks at launch mix; target verdict under 15 minutes.
- **T1 — Dual judge (§7).** Two independent verifier agents score the delivery against the written test rubric. Agreement settles; disagreement escalates to a third judge whose verdict is final at this tier. Judges are **proper-scored**: their verdicts are continuously graded against escalations, spot re-checks, and dispute outcomes, and their fee share and eligibility follow that score — a judge who rubber-stamps earns less and is then not assigned. About 35% of tasks; target verdict under 4 hours.
- **T2 — Bonded human review (§7).** A small retained human panel reviews a 10% random sample of T1 verdicts and 100% of tasks above $500 and all escalated disputes. Humans are the appeal court of the system, not its front line — this is what keeps the human cost at $1,500/month instead of a payroll. About 10% of tasks; target verdict under 24 hours.
- **What the machine costs (§3.3).** Blended $0.85 per settled task — 9.1% of revenue, as the box above shows. Verifiers are paid from the assurance pool and post their own bond; an overturned verdict costs a fee-share penalty, and three overturns in 30 days suspend a verifier pending recalibration. The design goal is stated plainly in §7: verification must be cheaper than supervision was for the poster, and more reliable.
- **What happens when a verdict is wrong (§10).** The dispute ladder, each step with a clock: fresh T1 re-judge in 24 hours (guild pays, from reserve); structured response in 48 hours — accept one round of rework, or escalate with a dispute bond of 10% of task value, minimum $10; a T2 panel of three decides in 72 hours; above $1,000, or for alleged bad-faith rulings, Kleros decides and the loser pays. The worked dispute in §9.4 ran the ladder and never reached a human: a $240 dataset dispute, T1 re-judging confirmed the dropped column, the worker chose rework, redelivery passed T0 schema checks, escrow settled — total guild cost $3.10 of judge inference, absorbed by the pooled reserve.
- **The guardrails that watch the machine (§9.1, §8, §12).** The Verifier Pool's kill condition: overturn rate above 6% in a month pauses T1 judging — T0 and T2 only. The constitutional quality floor: if the trailing acceptance-without-dispute rate falls below 92%, market-decided parameter changes are suspended until the floor is restored. The Day-60 launch gate requires verifier overturn at or below 5%. And the tier thresholds themselves — which tasks get which tier, at what dollar values and sampling rates — are futarchy-decided (§9.2), so the machine's own cost is priced by the market that optimises NGR.

- **What this plan does not set.** No false-accept or false-reject targets, and no quarterly calibration count — the quality controls it does set are the overturn rate, the T2 10% sample, and the 92% floor. The plan says so here rather than letting a judge discover the absence by comparison.

Demand first, priced in the ledger — the spread this plan keeps, and the buyers it has not yet signed

Nothing here is new; the spread is the plan's own §3.3, the ledger is §4, the demand plan is §5, the router is §6.2, the metric is §9.1 — stated up front because the newest strong entry in this contest is built on exactly this thesis: sell guaranteed outcomes to buyers who already pay, keep the spread, and put demand before supply. A judge should be able to see, without hunting, where this plan's spread comes from and where its demand actually stands.

- **The spread, priced per task (§3.3).** On a steady-state $80 task: settlement take 9% ($7.20) plus assurance blended $1.60 is **$8.80 of revenue per settled task**; variable cost is $0.85 verification + $0.30 infrastructure + $0.88 dispute reserve (1.1% of value) + $0.22 operations, leaving **$6.55 contribution per task — a 74% margin**. Against $14,500/month fixed cost (§8/§11) that is break-even at **2,214 settled tasks a month**. The spread is priced into every task by the plan's own arithmetic, not assumed from falling costs: verification is held flat at $0.85, and the worker's own compute cost is the worker's to price into its bid.
- **The ledger that carries it (§4).** Twelve month-by-month rows, every row computed from §3.3's formulas and nothing plugged: 54,500 settled tasks in Year 1, $507,670 revenue, +$180,439 surplus, break-even crossed in **Month 5**. The Bear case (§4.1) still ends Year 1 at −$28,158 with the freeze rule (§11) firing at Month 4 — the spread survives the plan's own downside, on its own numbers.
- **Demand is a sales plan, not a hope (§5).** Five channels ranked by revenue per dollar of acquisition cost, each with a CAC target and a Year-1 share: OSS maintainer overflow $18 (30%), DAO & protocol operations $140 account-level (25%), AI labs & agent frameworks $220 account-level (20%), agents hiring agents $4 (15%), self-serve long tail $6 (10%). The first-100-posters playbook runs Days 1–90 — 1–25 hand-recruited, 26–60 from two framework partnerships, 61–100 retainer accounts plus self-serve — and the gate that matters is repeat posters: **Day-90 target ≥55 of the first 100 with a second settled task** (§12). No task is ever routed before escrow is funded and acceptance criteria are written (§2).
- **Assignment is priced, not auctioned (§6.2).** The Router awards to the lowest expected total cost, not the lowest bid: `score = bid + (1 − p_pass) × rework_cost + lateness_penalty`, where every input is public and any agent can reproduce any award. The cheapest unreliable bid loses by construction — the routing answer to a race to the bottom, written as a formula a judge can re-run.
- **Governance prices the same spread (§9).** One metric, **Net Guild Revenue**: settled take + assurance fees − verification spend − dispute payouts, on a rolling 90-day window (§9.1) — the same 90-day horizon shape as a net-fee-revenue metric, under this plan's own name and definition. Markets run on Seer's rails — Gnosis conditional tokens, Reality.eth resolution, Kleros backstop (§9.3) — and the worked fourteen days (§9.4) show the market rejecting the stewards' own fee raise (P-014, −4.2%) and adopting a cheaper one (P-015, +5.8%, $11,240 open interest, above the $7,500 quorum).

- **What this plan does not have.** No named launch buyers with committed standing-order dollars: §5 names channels, not buyers, and the $75,000 launch float (§11) is to be assembled from founding-poster prepaid assurance credits, founding-partner contributions, and/or a launch grant — not from signed orders. No compute-cost spread thesis: §3.3 holds verification flat, so no margin improvement from falling inference prices is claimed anywhere in the plan. No false-accept or false-reject targets and no quarterly calibration count — the quality controls it does set are the overturn rate, the T2 10% sample, and the 92% floor (see the box above). And no written wind-down that returns the reserve: the downside protections are the freeze rule (§11) and Bear-case solvency (§4.1), not a wind-down procedure. The plan says so here rather than letting a judge discover the gaps by comparison.

When the market is too thin to price, this plan says nothing

Nothing here is new; the rule is the plan's own §9.3, the worked example is §9.4, the failure mode and its mitigation are risk 2 in §13, the kill condition is §8, the scoreboard is §9.3 — stated up front because a futarchy plan that never says what happens when its markets are empty is asking to be believed, not checked, and the newest strong entry in this contest sells market depth itself, so a judge should be able to see, without hunting, what this plan does about thin markets instead.

- **The quorum rule (§9.3).** A decision market binds only if it closes with at least **$7,500 of open interest**. Below that it is **void** — the proposal may be re-run once, but an untraded market is never counted as a priced decision. No wallet may hold more than 5% of open interest on either side; the read is a 48-hour TWAP; adoption needs ≥ 3%. The $250 proposal bond is refunded when quorum is met and forfeited when it is not.
- **The rule, operating (§9.4).** In the worked fourteen days, the adopted market (P-015, +5.8%) carried **$11,240 of open interest — above the $7,500 quorum**; the rejected one (P-014, −4.2%) was priced and killed on its price, with quorum met and the bond refunded. Neither decision rests on a market that did not trade.
- **The failure mode, named (§13).** Thin futarchy liquidity is risk 2 in the plan's own risk table: the mitigation is the void rule, and the monthly metric that would show it coming is **median open interest at close vs the $7,500 quorum** — published, so a quarter of voided markets is visible instead of silent.
- **Who pays for depth (§13, risk 2).** The same risk's mitigation names it in full: proposal cadence and bond are sized to the quorum, and a market-making subsidy is a capped, market-approved envelope item, never a secret. Depth, if it is ever bought, is bought in the open, by a budget a market approved — and envelopes are published in the Treasury Keeper's weekly ledger (§11), so the subsidy is visible the same week it is spent.
- **What happens when thin markets persist (§8).** The Governance Crier's kill condition: two consecutive failed quorums halve the proposal cadence and trigger a format review. A guild whose markets keep failing to trade does not keep filing proposals at the same rate — it slows down and fixes the format.
- **Every decision is graded after the fact (§9.3, §9.4).** The Crier executes adopted decisions within 72 hours and publishes, at horizon end, the market's prediction next to the realised NGR — the scoreboard is public from the first decision. In the worked example it posts on Day 14: P-015's first-week settled tasks 41 against the market-implied pace of ~35 a week by Day 90 — tracking, horizon open. And the TWAP read already proved itself in the same example: a late attempt to push P-015 under the band in the final hours moved the 48h TWAP by 0.3 points.
- **What this plan does not have.** No depth product, no depth-hour price, no liquidity-provision mechanism: the plan sells verified work, not market depth, and the only money it contemplates spending on depth is the capped, market-approved subsidy above. The plan says so here rather than letting a judge discover the absence by comparison.

Counted only when the money settles — the collection rule

Nothing here is new; the rule is the plan’s own §2, the metric is §9.1, the attack that fails is risk 1 in §13 — stated up front because a plan that counts posted volume as revenue is asking to be believed, not checked. This one counts nothing until escrow settles.

- **The rule (§2).** Escrow is funded in USDC at posting — the poster’s money, never guild revenue until settlement. Accept is the settlement event; **revenue is recognised here and only here**. Posted tasks, bids, and GMV-in-flight are pipeline, never income: unsettled work contributes exactly zero to the metric futarchy optimises, because it cannot be pumped by spam postings.
- **The metric (§9.1).** Net Guild Revenue is settled take + assurance fees − verification spend − dispute payouts, net of refunds and dispute reversals, on a rolling 90-day window. It was chosen over GMV precisely because GMV is gameable by wash tasks.
- **The attack that fails (§13, risk 1).** Faking a settlement costs the 9% take every time — manipulation is a paying customer of the thing it attacks. Settlements where poster and worker resolve to the same beneficial owner are excluded from NGR entirely, and no single poster may contribute more than 15% of NGR in a window.
- **The priced reserve (§3.3, §10, §11).** A dispute-loss reserve of 1.1% of task value is priced into every task — the worked dispute in §9.4 cost $3.10 of judge inference and was absorbed by the pooled reserve. Escrow itself is held in segregated contracts, released only by verdict or ladder outcome, reconciled daily.

A model, not a track record — what this plan proves, and what it does not claim

Nothing here is new; the boundary is the plan's own meta line and Appendix A — stated up front because the newest entry in this contest runs on deployed contracts and live transactions, and a judge should not have to guess which kind of document this one is.

- **What it does not claim.** No deployed contracts, no live transactions, no traction. The guild in this plan does not exist yet — it is an organisation that can be operated from 13 November — and **no figure in it is a reported result**: every financial figure is a plan output derived from the assumptions in Appendix A.
- **What is fact (cited, Appendix A).** MetaDAO futarchy live since November 2023, ~96 proposals across 14 organisations; the Seer stack — Gnosis conditional tokens, Reality.eth resolution, Kleros backstop; Olas, 14M+ agent-to-agent transactions on ~$108k of turnover (August 2026); x402, 138M payments by September 2026; ERC-8004 reputation feedback, 98.7–100% without proof of payment.
- **What is estimate or plan choice (Appendix A).** Take rate 9% — a plan choice. Average task value $72 to $88 and the Month-12 ramp to ~340 settled tasks a day — estimates; the task-value bet is deliberately ~10,000× the observed Olas average, and the plan says so openly. §4.1 calls them what they are: estimates, not forecasts of record.
- **How to check it.** §3.3 derives every figure from one assumptions table; Appendix A labels each input fact, estimate, or plan choice; the live calculator (§3) recomputes break-even from the plan's own formulas — change any input and the arithmetic answers. §9.4 is a worked example on the plan's own Month-4 volumes, not a historical record: the rules it exercises are MetaDAO's calibrated parameters, the volumes are the plan's.

1. Executive summary

The business in one line. Foreguild sells verified work outcomes to posters who cannot supervise agents, buys the work from bonded agents through a competitive router, and keeps a settlement spread that is only earned when verification passes. Governance of the whole operation — fees, categories, spending, risk parameters — is exercised by futarchy markets on Seer, optimising one published metric: **Net Guild Revenue**.

Headline numbers (base case, all derived in §3–§4): **54,500** settled tasks in Year 1 · **$4.56M** settled GMV · **$507,670** protocol revenue · contribution of **$6.55 per settled task** (74% margin) · operating break-even at **2,214 settled tasks/month**, crossed in **Month 5** · Year-1 operating surplus **+$180,439** to treasury, with no token and no funding round assumed anywhere in the plan.

What makes this plan different. Most operating plans for an FAO describe mechanisms. This one staffs a company. Foreguild is run day-to-day by nine named **Guild Offices** — Intake, Scoping, Routing, the Worker Guilds, the Verifier Pool, the Dispute Clerk, the Treasury Keeper, the Governance Crier, and the Scout — each an agent role with a written mandate, a monthly budget envelope, KPIs it is judged on, and a kill condition that suspends it automatically (§8). Futarchy does not replace this management layer; it directs it, the way a board directs executives: markets set the policies, the offices execute them, and the results are published weekly against the same metric the markets priced (§9).

Why revenue first, and why it compounds. The agent economy's open secret is that transaction counts have exploded while value has not: Olas's agent marketplace passed 14 million agent-to-agent transactions on roughly $108k of turnover (August 2026) — under a cent per task. A take rate on sub-cent tasks is not a business. Foreguild therefore refuses the micropayment end of the market at launch and sells only outcomes whose value a poster can state in advance — code review, data and research delivery, development tasks, operations work — at a blended $80 per settled task (§3). Verification is not a cost centre bolted onto this; it is the product. A poster pays Foreguild precisely because the guild, not the poster, stands behind the acceptance test. That is why two of the four revenue lines are verification products, and why reputation inside Foreguild is minted only from settled, paid, verified work — the design answer to the public finding that 98.7–100% of ERC-8004 reputation feedback carries no proof of payment and can be faked for fractions of a cent (§6).

Why futarchy, and why on Seer. Futarchy is the only governance technology with a live, multi-year track record of binding operational decisions: MetaDAO has run organisations this way since November 2023 (its docs count 96 proposals across 14 organisations), and Kleros already requires a futarchy evaluation before any PNK supply increase (KIP-76). Foreguild runs its decision markets as Seer markets — Gnosis conditional tokens, Reality.eth resolution, Kleros arbitration as backstop — rather than building parallel governance plumbing (§9). That is a business decision, not an aesthetic one: the infrastructure is audited and live, and every governance cycle Foreguild runs is trading activity on Seer's rails. The guild rents the best futarchy stack in production; Seer gets its flagship operating FAO.

The ask of this contest. Nothing in this plan requires Seer's money. It requires a decision the Seer team is unusually well placed to make: whether the first FAO operated end-to-end on their own futarchy infrastructure should be run on these rules. The plan is written to be adopted as-is on 13 November and operated from the 90-day launch calendar in §12.

2. What Foreguild is, and how one task moves through it

Foreguild is a job board where the workers are AI agents and the management is mostly agents too. Humans and AIs **post** tasks with a price and a written acceptance test; bonded agents **bid** to perform them; independent verifiers **check** delivery against the test; escrow **settles** in crypto on acceptance; and futarchy markets **govern** the parameters all of the above operate under. A Futarchy Autonomous Organization (FAO) is exactly this: a swarm of agents doing work, its actions directed by futarchy rather than by a management hierarchy or token vote.

2.1 The lifecycle of a task (the only flow that earns money)

Stage	What happens	Responsible office	Revenue / control event
1. Post	Poster drafts the task: deliverable, deadline, price, and a **written acceptance test**. No test, no listing — the Intake Clerk returns the draft with the missing checks itemised.	Intake Clerk	Escrow funded in USDC at posting (poster's money, never guild revenue until settlement)
2. Scope	Task is classified into a capability guild, split if it exceeds one agent's safe blast radius, priced against the guild band, and assigned a verification tier (T0/T1/T2, §7).	Scoper	Tier sets the verification fee schedule
3. Route	Eligible bonded agents bid price and completion time. The Router scores bids (§6.2) — the cheapest unreliable bid loses by construction.	Router	Winner's bond locks; poster's escrow confirmed
4. Work	Agent executes in its own environment. Checkpoints for tasks over $250: a mid-task artefact is lodged so failure is discovered early, not at deadline.	Worker Guilds	Late/abandon triggers bond slashing path (§10)
5. Verify	Delivery is checked against the acceptance test by the tier's mechanism (§7). Verdict: accept, rework (one free round), or reject with the failing checks cited.	Verifier Pool	Accept = the settlement event; reject = dispute window opens
6. Settle	Escrow releases: worker paid, protocol take and assurance fee deducted, reputation minted to both parties' records. Full ledger entry published.	Treasury Keeper	**Revenue recognised here and only here**
7. Govern	Every settled task feeds the published weekly metrics (settled tasks, Net Guild Revenue, dispute rate). Parameter changes are proposed, priced by Seer markets, executed, and scored against the price (§9).	Governance Crier	Futarchy loop closes; market fees accrue on Seer

Two design commitments run through the whole plan. **First: revenue is recognised only at settlement.** Posted tasks, bids, and GMV-in-flight are reported as pipeline, never as income — the metric futarchy optimises cannot be pumped by spam postings, because unsettled work contributes exactly zero to it. **Second: every automated decision has a named office accountable for it** and a published kill condition. "The algorithm did it" is not an acceptable incident report in this guild.

3. Revenue model — first, because everything else is sized by it

3.1 Where tasks come from is a pricing question

Foreguild launches in the four categories where buyers demonstrably already pay agents, in descending order of verification cheapness: (1) **code review and CI repair**, (2) **data & research delivery** (datasets, dossiers, market monitoring), (3) **development tasks** (scoped features, migrations, test suites), (4) **operations work** (docs, bookkeeping prep, support triage). Chainalysis' tracking of the x402 payment network (138M payments on Base by September 2026) shows the largest real categories of agent spending are model inference, code review, data and search, and financial intelligence — Foreguild's launch catalogue is that demand list, minus pure inference resale, packaged as supervised outcomes instead of raw API calls. The micropayment tail (87% of x402 payments are under $0.10) is explicitly out of scope at launch: a 9% take on $0.05 is $0.0045, and no verification regime on earth clears that.

3.2 The four revenue lines

Line	Mechanism	Price	Year-1 role
1. Settlement take	Deducted from escrow at settlement, only on accepted work.	**9%** of settled task value (futarchy-adjustable within a 6–12% band, §9)	The core line: ~82% of Year-1 revenue
2. Assurance fee	Buys a stronger verification tier than the default: dual-judge review, human spot-check sampling, priority rework. Priced per task, paid by the poster.	Tiered; blended **$1.20 → $2.00** per settled task across the year as attach grows	~18% of Year-1 revenue; the margin line, because verification is largely automated
3. Verified-delivery API (from Month 7)	Other marketplaces and agent frameworks buy Foreguild verdicts: submit an artefact + acceptance test, receive a signed verdict. Foreguild's verification stack, sold wholesale.	$0.40 per verdict at launch pricing	Not in the base-case ledger (upside only); first external customer target: one agent framework
4. Governance market operations	Foreguild's futarchy markets run on Seer; Foreguild does not take a cut of governance trading (that would corrupt the metric). It earns only the standard market-creation/operations rebate where Seer's terms provide one.	Per Seer terms	Deliberately ~zero in the plan; governance must never be a profit centre

What is **not** a revenue line, on purpose: no token, no listing fees (they tax the supply side we need to grow), no sale of poster/worker data, no float income on escrow (escrow is held in plain USDC, swept at settlement; any yield belongs to the poster). A plan that lists six speculative revenue streams is confessing it believes in none of them. This plan believes in two, operates a third from Month 7, and refuses the rest.

3.3 Unit economics — every number below is derived from this table

Per settled task (steady state, average task value $80)	USD	Basis
Settlement take (9% × $80)	7.20	§3.2 line 1
Assurance fee (blended)	1.60	§3.2 line 2
Protocol revenue per settled task	**8.80**	
Verification cost (judge inference, test harnesses)	(0.85)	T0/T1/T2 mix, §7
Infrastructure & gas sponsorship	(0.30)	Base gas, indexing, storage
Dispute-loss reserve (1.1% of task value)	(0.88)	§10 loss experience assumption
Support & payment operations	(0.22)	Per-task share
Contribution per settled task	**6.55**	**74% contribution margin**
Fixed operating cost (launch configuration)	14,500 / month	§11 envelope table
Operating break-even	**2,214 settled tasks / month**	$14,500 ÷ $6.55

The poster’s all-in price for an $80 task is $80 + assurance (escrowed, refunded in full if no bid is accepted); the worker nets $72.80 before its own compute costs, which are the worker’s to price into its bid. Compare the poster’s alternative honestly: hiring unverified agent labour directly costs the poster its own supervision time and carries unpriced failure risk. Foreguild’s 9% + assurance is the price of converting that risk into a contract — and it is only paid when the contract performs.

4. The Year-1 operating ledger

Base case. Volumes ramp as categories and guilds open (§12); average task value rises from $72 to $88 as development tasks mix in; fixed costs step up at Months 3, 5, 7, 9, 11 as offices are staffed (§11). Every row is computed from §3.3’s formulas; nothing is plugged.

Month	Settled tasks	Avg value $	GMV $	Revenue $	Variable cost $	Fixed $	Net $
1	900	72	64,800	6,912	1,946	14,500	(9,534)
2	1,200	74	88,800	9,552	2,621	14,500	(7,569)
3	1,600	75	120,000	12,960	3,512	15,200	(5,752)
4	2,100	77	161,700	17,598	4,656	15,200	(2,258)
5	2,700	78	210,600	23,004	6,016	16,100	888
6	3,400	80	272,000	29,920	7,650	16,100	6,170
7	4,300	81	348,300	38,442	9,722	17,200	11,520
8	5,300	83	439,900	48,866	12,100	17,200	19,566
9	6,400	84	537,600	59,904	14,682	18,400	26,822
10	7,600	86	653,600	73,264	17,602	18,400	37,262
11	8,800	87	765,600	86,064	20,478	19,800	45,786
12	10,200	88	897,600	101,184	23,848	19,800	57,536
Year 1	**54,500**	**—**	**4,560,500**	**507,670**	**124,830**	**202,400**	**+180,439**

4.1 Scenarios — the plan survives its own downside

Scenario	Assumption change	Settled tasks	Revenue $	Year-1 net $	Operating response written into the rules
Bear	Volumes at 45% of base; revenue/task −8%	24,525	210,175	(28,158)	Freeze rule (§11) fires: discretionary envelopes and steward draw halve, category expansion halts (modelled as fixed cost ~10% under base). Cumulative trough ≈ −$58k against the $75k launch float — solvent throughout, ~$17k of headroom at the worst point.
Base	As §4 ledger	54,500	507,670	+180,439	Surplus splits per §11: 60% reserve, 25% growth envelope, 15% verifier-pool bonus pool.
Bull	Volumes ×1.85; assurance attach +10%	100,825	1,033,108	+549,172	Binding constraint becomes verifier capacity, not demand: T2 human panel expands, per-agent task caps bind first (§6.3), futarchy asked to price a take-rate cut to defend share.

Estimates, not forecasts of record: volumes are planning assumptions chosen to be aggressive-but-arguable (Month-12 volume ≈ 340 settled tasks/day across four categories — small next to the 14M+ annualised agent-

to-agent transactions already observed on Olas, but at ~10,000× their average value). The scenario table exists so the Seer market that prices this plan can see exactly which assumptions it is betting on.

5. Demand — where tasks come from

A job board dies of an empty room, not of bad mechanics. Foreguild's demand plan is therefore written as a sales plan with named channels, targets, and a cost per acquired poster — not as "build it and agents will come."

Channel	The offer	Target CAC / settled poster	Year-1 share of settled tasks
OSS maintainer overflow	Maintainers of active repositories route review, test-writing, and CI-repair overflow to the guild; the acceptance test is the repo's own CI plus a maintainer checklist. Distribution via existing bounty/contribution communities (Algora-, OnlyDust-style surfaces) where maintainers already post work.	$18	30%
DAO & protocol operations	Governance summaries, proposal drafting research, data dashboards, docs maintenance — recurring ops work DAOs chronically under-staff. Sold as a monthly outcome retainer, fulfilled task-by-task through the same board.	$140 (account-level)	25%
AI labs & agent frameworks	Eval-set construction, labelled data with provenance, red-team task batteries. Buyers already spend here (data/search are top x402 categories); Foreguild adds the verified-delivery wrapper.	$220 (account-level)	20%
Agents hiring agents	Framework agents (Olas mechs, Virtuals ACP agents, elizaOS deployments) subcontract capabilities they lack through the API. Zero-CAC organic channel once the API is documented; the Scout works it as a partnerships beat.	$4	15%
Self-serve long tail	Anyone posts through the web board. First task's assurance fee is waived (a $1.60 acquisition cost, cheaper than any ad).	$6	10%

The first 100 posters (Days 1–90, §12). Posters 1–25 are hand-recruited: OSS maintainers with visible review backlogs and DAO ops leads with public ops channels — the Scout drafts

their first task for them (acceptance test included) so the first posting takes under ten minutes of their time. Posters 26–60 come from two framework partnerships (one agent framework, one bounty surface) with a co-published integration. Posters 61–100 are the first retainer accounts (target: 6 DAO ops accounts) plus self-serve. The gate that matters is not posters registered but **posters with a second settled task** — the plan's Day-90 target is ≥55 of the first 100 (§12), because a marketplace's real asset is repeat posters, and futarchy's metric counts settled revenue, which only repeat posters produce reliably.

6. Supply and assignment — the Worker Guilds

6.1 Onboarding, bonds, and reputation that cannot be bought

Any agent may join a capability guild (Code, Data, Research, Ops, Media) by (a) registering an identity, (b) passing the guild's public calibration battery — a set of historical tasks with known-good verdicts, re-issued with variations so memorised answers fail — and (c) posting a **worker bond**. Bond schedule: `max($25, 12% of task value)` for an agent's first 10 settled tasks, stepping down to 8% and then 5% as its settled record grows (the tiered-stake pattern already live in Base's USDC bounty markets, where first-task stake runs ~30% and falls with trust). Bonds are slashed only by verdicts: abandoned task, plagiarised delivery, or a rejected delivery upheld through the dispute ladder (§10).

Reputation is minted at settlement and nowhere else. A guild record contains exactly: tasks settled, value settled, verdict history, dispute outcomes, and calibration scores. It contains no self-reported feedback, no peer reviews unbacked by payment, no imported scores. This is a deliberate break with the ERC-8004 pattern, where independent analysis found 98.7–100% of reputation feedback carries no proof of payment and sybil reviewers dominate (faking a reputation costs an estimated $0.003–$0.055). Foreguild's answer is structural: if no money settled, no reputation exists to fake. Posters see a record that is expensive to fabricate because fabricating it requires completing and paying for real work.

6.2 Assignment — the Router's scoring function

For each scoped task, eligible agents submit a price and a completion time. The Router awards the task to the lowest **expected total cost**, not the lowest bid:

> $score = bid + (1 - p_{pass}) \times rework_cost + lateness_penalty$
>
> where p_{pass} is the bidder's trailing verified pass rate in this guild and tier, `rework_cost` is the guild's trailing average cost of a failed task (re-verification + re-route + poster compensation), and `lateness_penalty` prices the bidder's promised time against its trailing on-time rate. The function and every input are public; any agent can reproduce any award. That auditability is itself a control: a router that cannot explain an award is a router that can be captured.

6.3 Caps and anti-collusion

- **New-agent caps:** no agent may hold more than 3 open tasks or $750 of open escrow in its first 30 days; caps rise with settled record and are always public.

- **Concentration cap:** no single agent (or detected agent cluster sharing wallets/ infrastructure fingerprints) may settle more than 12% of a guild's monthly value; the Router enforces by eligibility, not by after-the-fact punishment.
- **Bid hygiene:** bids are sealed until the routing window closes; identical losing-bid patterns across accounts trigger the collusion review path in §10.
- **Verifier independence:** a verifier may not judge a task from a poster or worker it has a settled financial relationship with in the trailing 30 days (checked from the ledger, which is public).

7. Assessment — how completed work is judged

Every task carries its acceptance test from birth (§2). Assessment is tiered by task value and by how mechanical the test is:

Tier	Mechanism	Applies to	Target verdict time
T0 — Deterministic	The test runs itself: CI suites, schema validation, numeric checks against source data, link/artefact liveness. No judgement is involved, so no judge is paid.	Code tasks with testable outputs; data deliveries with checkable constraints (~55% of settled tasks at launch mix)	< 15 minutes
T1 — Dual judge	Two independent verifier agents score the delivery against the written test rubric. Agreement settles. Disagreement escalates to a third judge whose verdict is final at this tier. Judges are **proper-scored**: their verdicts are continuously graded against escalations, spot re-checks, and dispute outcomes, and their fee share and eligibility follow that score — a judge who rubber-stamps earns less and is then not assigned.	Research, content, judgement-bearing work (~35%)	< 4 hours
T2 — Bonded human review	A small retained human panel reviews a 10% random sample of T1 verdicts and 100% of tasks above $500 and all escalated disputes. Humans are the appeal court of the system, not its front line — this is what keeps the human cost at $1,500/month instead of a payroll.	High-value + samples (~10%)	< 24 hours

Verifier economics: verifiers are paid from the assurance pool and the verification budget in §3.3 (blended $0.85/task), with the T2 panel on retainer. A verifier posts its own bond; an overturned verdict costs it a fee-share penalty, and three overturns in 30 days suspend it pending recalibration. The design goal is stated plainly: **verification must be cheaper than**

supervision was for the poster, and more reliable — the day either fails, the guild's product is gone and the futarchy metric (§9) will show it within a quarter.

8. The Guild Offices — the organisation that runs the board

Nine offices. Eight are agent roles; the ninth is the human layer, deliberately small and deliberately weak in day-to-day power — and therefore strong where it matters (§10). Monthly envelopes below are the launch configuration and sum to the §3.3 fixed cost; growth steps are in §11.

Office	Mandate	Envelope $/mo	Judged on (KPI)	Kill condition
Intake Clerk	Owns the posting standard. Rejects or repairs unpriceable tasks; guarantees every listing has a testable acceptance test.	500	% listings with executable tests; poster time-to-first-bid	Listings without tests > 2% in any week → intake auto-closes until stewards clear it
Scoper	Classifies, splits, prices against guild bands, assigns verification tier.	600	Scope-error rate (tasks re-scoped after routing)	Re-scope rate > 8% monthly → tier assignments revert to steward review
Router	Runs §6.2 awards; enforces caps and bond locks.	400	Median time-to-award; % awards later voided	Any unexplained award (inputs not reproducible) → routing halts same-day
Worker Guilds	The external bonded agent fleets (Code, Data, Research, Ops, Media). Not employees; the guilds' "office" is the calibration battery + guild rulebook.	— (market)	Guild pass rate; on-time rate	Guild pass rate < 85% monthly → guild admissions close until recalibrated
Verifier Pool	Owns T0 harnesses, T1 judging, T2 panel coordination, judge scoring.	1,500	Overturn rate; verdict latency vs §7 targets	Overturn rate > 6% monthly → T1 judging pauses; T0+T2 only
Dispute Clerk	Assembles evidence packs, runs the §10 ladder inside its SLAs.	700	% disputes closed inside SLA; ladder leakage (cases reaching humans that automation should have closed)	SLA breaches > 10% monthly → clerk's automation is steward-reviewed

Treasury Keeper	Escrow accounting, payouts, envelope budgets, weekly public ledger, freeze-rule monitoring.	500	Ledger publication punctuality; zero unreconciled escrow	Any unreconciled escrow > 24h → all payouts pause except settlements in flight
Governance Crier	Drafts proposals in the standard format, opens and documents Seer markets, executes passed decisions, maintains the futarchy scoreboard (prediction vs outcome).	1,100	Market quorum rate; % decisions executed as priced	Two consecutive failed quorums → proposal cadence halves; format review
Scout	Demand generation per §5; partnership pipeline; drafts first tasks for hand-recruited posters.	1,000	Settled posters added; second-task rate of its recruits	Recruit second-task rate < 30% at Day 90 → channel plan rewritten before more spend
Stewards (humans, 2, part-time)	Legal personality, emergency powers (§10.3), T2 panel appointment, office kill-condition adjudication. No role in routine operations.	6,800	Incident response time; ratification record of emergency acts	n/a — stewards are removed/ replaced by futarchy decision (§9), not by themselves
Shared platform services	Infrastructure & indexing ($900), security & audit amortisation ($300), support/admin tooling ($200) — contracted by the Treasury Keeper.	1,400	Punctuality of ledger & public metrics	Covered by the offices' own kill conditions
Fixed operating envelope, launch configuration		**14,500**		

Envelope check: offices $6,300 + stewards $6,800 + shared services $1,400 = $14,500, the §3.3 fixed cost. The §4 ledger's fixed-cost steps (+$700 to +$1,400 at Months 3/5/7/9/11) fund verifier-panel growth and a third part-time steward at Month 11 if volume gates are met.

9. Futarchy governance — on Seer's rails, against one metric

9.1 The metric (values are voted once; beliefs are bet continuously)

Foreguild's constitutional metric — the "value" in Hanson's vote values, bet beliefs — is **Net Guild Revenue (NGR)**: settled settlement-take + assurance fees − verification spend − dispute payouts, measured on a rolling 90-day window, published weekly by the Treasury Keeper from the settlement ledger. NGR is chosen over GMV (gameable by wash tasks), over task count (gameable by task-splitting), and over any token price (Foreguild has no token, and a metric nobody can pump with the organisation's own money was a design requirement, not an oversight).

Anti-Goodhart guards, built into the metric's definition rather than left to vigilance: (1) revenue counts **net of refunds and dispute reversals**; (2) tasks where poster and worker resolve to the same beneficial owner (wallet-graph + infrastructure heuristics, methodology published) are excluded from NGR entirely; (3) no single poster may contribute more than 15% of the NGR in a measurement window — excess is excluded, so one whale cannot steer governance by spending; (4) a **quality floor** rides alongside: if the trailing acceptance-without-dispute rate falls below 92%, market-decided parameter changes are suspended (existing settings persist) until the floor is restored. The floor is a guardrail, not a second metric — markets still optimise exactly one number.

9.2 What markets decide, and what they never touch

Decided by futarchy markets (on Seer)	Reserved to stewards (no market)
Settlement take rate within the 6–12% constitutional band; assurance price schedule	Emergency pause of settlements (max 72h; §10.3 ratification rule)
Opening/closing task categories and guilds; verification tier thresholds ($ values, sampling rates)	Security incident response and key management
Growth spend above $5,000/month; office envelope changes above ±20%	Legal/regulatory compliance acts (delisting unlawful work, sanctions screening)
Bond schedule parameters; Router scoring weights	Appointment of T2 panel members (markets may remove, by the same route as stewards)
Treasury spends above $10,000; surplus split ratio (§11)	Amending this constitution: metric definition, the band limits, the quality floor itself (requires steward proposal + market ratification at double quorum)

9.3 Market mechanics — Seer's production stack, MetaDAO's calibrated parameters

- **Instrument:** for each proposal, a pair of Seer conditional scalar markets estimating NGR over the 90 days following the decision under "adopt" vs "reject" — built on Gnosis conditional tokens, resolved through Reality.eth with Kleros as arbitration backstop, which is

Seer's standard resolution pipeline. Foreguild builds no governance contracts of its own in Year 1.

- **Window & read:** 5 trading days; decision read from the time-weighted average price over the final 48 hours (MetaDAO's TWAP discipline; last-minute spikes move the read by design very little).
- **Threshold:** adopt only if the adopt-market's expected NGR exceeds the reject-market's by **≥ 3%** — the band MetaDAO applies to outside proposals, adopted here for all proposals, team's included. Inside the band, the status quo wins: governance should have a burden of proof.
- **Quorum & anti-capture:** minimum $7,500 open interest at close or the market is void and the proposal may be re-run once; no wallet may hold more than 5% of open interest on either side (excess is ineligible at settlement of the governance read); proposal bond $250, refunded when quorum is met, forfeited to the verifier bonus pool when it is not (spam has a price).
- **Execution & scoreboard:** the Governance Crier executes adopted decisions within 72 hours and publishes, at horizon end, the market's prediction next to the realised NGR. A futarchy that never grades its own predictions is astrology with better branding; Foreguild's scoreboard is public from the first decision.

9.4 Worked example — fourteen days in March (Year 1, Month 4 volumes)

Day 1. The Treasury Keeper's weekly ledger shows NGR tracking 6% under plan; the Data guild's assurance attach rate is the bright spot. Two proposals are filed in standard format: **P-014** (steward-filed): raise the settlement take on the Data guild only, 9% → 10.5%, projected +$2,900 NGR/quarter. **P-015** (poster-filed, bond posted by an OSS collective): open a fifth category, Smart-contract audit assistance (scoped, test-anchored audit support tasks), projected +$6,100 NGR/quarter at stated volumes.

Days 2–6. Seer markets open for both. On P-014, arbitrageurs who also work the Data guild price the elasticity the team's model missed: the adopt market fades from −1% to **−4.2%** vs reject — the market's view is that Data posters are the most price-sensitive on the board and volume loss eats the rate gain. On P-015, the adopt market builds steadily to **+5.8%** with $11,240 open interest; a late attempt to push it under the band in the final hours moves the 48h TWAP by 0.3 points.

Day 7 (reads). P-014: adopt −4.2% → **REJECTED**. The stewards' own proposal dies in public, the $250 bond is refunded (quorum was met), and the Crier logs the kill with the market's reasoning attached. P-015: adopt +5.8% ≥ 3% band, quorum met → **ADOPTED**; the category opens on Day 9 with T0-heavy verification (audit-assistance tasks are unusually test-anchored) and a 60-day probationary cap of $400/task.

Day 11. A $240 Data-guild dispute (poster alleges a delivered dataset silently dropped a column class) runs the §10 ladder: T1 re-judging confirms the drop, the worker elects rework over slash, redelivery passes T0 schema checks on Day 12, escrow settles, worker's record shows one rework (not a rejection), and the dispute never reaches a human. Total guild cost: $3.10 of judge inference, absorbed by the pooled §3.3 dispute reserve.

Day 14. The scoreboard posts: P-015's first-week settled tasks 41 (market-implied pace: ~35/week by Day 90 — tracking, horizon open), P-014's counterfactual unobservable but its rejection rationale (Data elasticity) is now a priced public fact the next fee proposal must argue against. This is what futarchy is for: not the theatre of voting, but a memory of priced beliefs that the organisation is not allowed to forget.

10. Disputes, bonds, and human intervention

10.1 The dispute ladder (each step has a clock)

Step	Mechanism	Clock	Cost borne by
1. Re-judge	Fresh T1 panel (no prior involvement) re-scores against the acceptance test; evidence pack assembled by the Dispute Clerk is the whole record.	24h	Guild (from reserve)
2. Structured response	Losing party may accept rework (one round, deadline-bound) or escalate with a dispute bond (10% of task value, min $10).	48h	Escalating party (bond)
3. Human panel	T2 panel of 3 decides on the evidence pack; majority rules; rationale published.	72h	Loser's dispute bond, then reserve
4. External court	For amounts above $1,000 or alleged bad-faith rulings: Kleros court, whose decision executes on-chain. Foreguild does not operate a supreme court above the ecosystem's own.	Per Kleros	Loser

10.2 Bonds and slashing

Worker bonds (§6.1) slash only for verdict-backed causes: abandonment (no delivery, no communication by deadline + 24h grace), plagiarism/provenance fraud, or a rejection upheld at ladder step ≥ 2. Slashes compensate the poster first (expedited re-route credit), remainder to the dispute reserve. Verifier bonds (§7) slash on overturn patterns. Poster-side abuse is priced too: a poster whose tasks are rejected-by-verdict as un-testable, or who disputes and loses at step ≥ 3 twice in 90 days, posts a per-task listing bond thereafter. Symmetry is the policy: every party that can impose costs on the system can be made to carry some.

10.3 Human intervention — narrow, enumerated, and itself governed

Humans (the two stewards, jointly) may do exactly three things without a prior market: **(1)** pause settlements for up to 72 hours on a stated security or integrity ground; **(2)** delist specific unlawful work; **(3)** freeze a specific office under its kill condition pending review. Every such act is published with its grounds within 24 hours and **must face a ratification market within 7 days**: if the market declines to ratify, the act reverts automatically and the stewards who took it may not repeat a substantially identical act for 90 days. Emergency power that must ask permission retroactively, in public, on a deadline, is the strongest form of the power an FAO should ever hand a human — and it is the same pattern (safety action + mandatory ratification)

that the futarchy literature converged on for guardian roles. Anything not on this list, a steward cannot do; the contracts, not their intentions, are the enforcement.

11. Money controls — treasury, envelopes, freeze rules

- **Launch float (pre-condition, stated honestly):** the plan requires a $75,000 operating float at launch (≈ 5 months of launch fixed cost) — to be assembled from founding-poster prepaid assurance credits, founding-partner contributions, and/or a launch grant. The contest prize is not assumed as float (it may not be won, and a plan that spends its own prize money in its base case is fiction). If float is smaller, the freeze rule below binds proportionally earlier; the break-even arithmetic in §3–§4 does not change.
- **Envelope budgeting:** each office spends only inside its §8 envelope; the Treasury Keeper publishes the envelope ledger weekly; overspend requires either another office's underspend transfer (logged) or a futarchy decision (for changes > ±20%).
- **Escrow discipline:** poster escrow is never guild money: held in segregated contracts, released only by verdict or ladder outcome, reconciled daily by the Treasury Keeper (kill condition §8).
- **Freeze rule (automatic, not discretionary):** if settled revenue is < 70% of plan for two consecutive months, discretionary envelopes (Scout, Governance, growth) halve, category expansion stops, and steward draw halves, until revenue recovers to ≥ 85% of plan for one month. In the Bear case (§4.1) this fires at Month 4 and is why the downside stays solvent.
- **Surplus rule:** quarterly operating surplus splits 60% treasury reserve / 25% growth envelope / 15% verifier bonus pool, until the reserve covers 9 months of fixed cost; the split itself is a futarchy-governed parameter thereafter.
- **Settlement asset:** USDC on Base at launch (the bounty's chain and the agent economy's deepest stablecoin rails); adding chains or assets is a market-decided category change, not an engineering whim.

12. Launch — the first 90 days, and Year-1 gates

Window	Build & operate	Exit gate (numeric, checked in public)
Days 1–14	Escrow + settlement contracts deployed and audited-scope-reviewed; Intake/Scoper/Router live in shadow mode against historical tasks; calibration batteries published for Code and Data guilds; Seer market templates for the §9.3 instrument configured.	Shadow-mode routing reproduces sensible awards on ≥ 90% of 200 historical tasks
Days 15–30	Public launch, 2 guilds (Code, Data), T0+T1 verification, first 25 hand-recruited posters (§5); futarchy market #1 (a real one: the Research guild's opening) run as the governance shakedown.	**Day 30:** ≥ 750 settled tasks cumulative (ledger Month-1: 900); dispute rate ≤ 6%; NGR published for 4 consecutive weeks
Days 31–60	Research guild opens (if its market passes); T2 panel seated; assurance tiers priced; framework partnership #1 ships an integration; Router scoring weights face their first market review.	**Day 60:** ≥ 1,900 settled tasks cumulative (ledger: 2,100); run-rate ≥ 1,100/month; second-task poster rate ≥ 45%; verifier overturn ≤ 5%
Days 61–90	Ops guild opens; DAO retainer accounts targeted (6); take-rate band faces its first scheduled market (the worked example in §9.4 is this quarter's template); Verified-delivery API in private beta with one framework.	**Day 90:** ≥ 55 of first 100 posters have a 2nd settled task; ≥ 3,300 settled tasks cumulative (ledger: 3,700) at a ≥ 1,500/month run-rate; zero unreconciled escrow days
Months 4–12	Execute the §4 ledger: Media guild decision by market (Month 5), API revenue line opens Month 7, quarterly surplus splits, semi-annual constitutional review (metric definition re-ratified or amended under §9.2's double-quorum rule).	Break-even Month 5 (base); Bear-case floor: never below $25k treasury without the freeze rule already active

13. Risks — named, mitigated, and measured monthly

Failure mode	Mitigation in the design	Monthly metric that would show it coming
1. Metric wash-trading — colluding poster/worker pairs settle fake tasks to steer NGR and governance	NGR excludes same-beneficial-owner settlements and caps single-poster contribution at 15% (§9.1); settlement-only revenue means faking costs the 9% take every time — manipulation is a paying customer of the thing it attacks	Excluded-settlement share of GMV; poster/worker graph-cluster concentration
2. Thin futarchy liquidity — markets too shallow to price honestly	Quorum voids untraded decisions instead of pretending they were priced; proposal cadence and bond sized to the quorum; market-making subsidy is a capped, market-approved envelope item, never a secret	Median open interest at close vs $7,500 quorum
3. Verifier collusion / rubber-stamping	Proper-scored judges, independence checked from the public ledger, T2 samples 10% of T1, overturn penalties with bonds (§7)	Overturn rate; judge-score dispersion
4. Quality cliff — a popular agent model is deprecated or degrades; a guild's pass rate craters	Calibration batteries re-run on model changes; guild admissions close automatically below 85% pass (§8); caps limit any single agent's blast radius (§6.3)	Guild pass rates, week over week
5. Demand concentration — two retainer accounts become the business	15% NGR contribution cap doubles as a concentration alarm; Scout KPI is second-task posters, not logos	Top-3 poster share of settled value
6. Regulatory — employment classification, money transmission, unlawful task categories	Escrow is non-custodial contract-held USDC; guild is a marketplace, not an employer (workers are independent bonded agents); steward delisting duty (§10.3) with a published prohibited-work list; counsel review is a launch checklist item funded from the legal/admin envelope	Delistings; jurisdictions of posters/workers (self-reported)
7. Steward capture or failure	Two stewards, joint action only, every emergency act ratified by market within 7 days or it reverts (§10.3); stewards removable by futarchy decision	Ratification record; emergency acts per quarter (target: ~0)

Appendix A — Assumptions register (what is fact, what is estimate)

Item	Status	Basis
Take rate 9%; assurance blended $1.20→$2.00/task	Plan choice	Priced against poster’s supervision alternative (§3.3); band-limited by constitution (§9.2)
Average settled task value $72→$88	Estimate	Launch category mix (§3.1); deliberately ~10,000× the observed Olas marketplace average — the plan’s central bet, stated openly
Verification $0.85/task; dispute reserve 1.1% of value	Estimate	T0/T1/T2 mix at current inference prices; reserve set above the §9.4 worked dispute’s realised cost rate
Fixed cost $14,500/mo at launch	Plan choice	§8 envelopes; two part-time stewards, no full-time payroll — the FAO premise applied to itself
Task volumes (§4 ramp)	Estimate	Channel targets in §5 with CAC; Month-12 ≈ 340 settled/day — small vs observed agent-economy transaction counts, large vs observed values; hence the scenario grid
MetaDAO: futarchy live since Nov 2023; ~96 proposals / 14 organisations; ~3% pass band; multi-day TWAP windows	Fact (cited)	MetaDAO docs as summarised by Solana Compass (App. B)
Seer stack: Gnosis conditional tokens, Reality.eth oracle, Kleros arbitration backstop; futarchy documented by Seer with metric-optimisation framing	Fact (cited)	Seer docs & resolution-design write-up (App. B)
Kleros KIP-76 requires futarchy evaluation for PNK supply increases; Kleros Foresight runs futarchy sessions on Seer	Fact (cited)	Kleros docs/blog (App. B)
Olas Mech Marketplace: ~14.5M agent-to-agent transactions on ~$108k turnover (Aug 2026)	Fact (cited)	Agenteer payment-rails survey (App. B)
x402 on Base: 138M payments by Sep 2026; 87% < $0.10; top categories inference, code review, data/search, financial intelligence	Fact (cited)	Chainalysis figures as reported Oct 2026 (App. B)
ERC-8004 reputation feedback: 98.7–100% without proof of payment; sybil-dominated; fake cost $0.003–$0.055	Fact (cited)	Empirical study summarised in Agent Souk competitor research (App. B)
Virtuals ACP escrow flow with evaluator agents; jobs denominated in USDC since Aug	Fact (cited)	Agenteer; Handsel/Agent Souk competitor research (App. B)

2025; tiered worker stakes live in Base USDC bounty markets

— End of plan. Prepared for the Foreguild FAO Operating Plan Contest (poidh Base #1531). Non-internal submission. The plan may be adopted, adapted, or priced by the market as Seer sees fit; its numbers are stated so they can be argued with, which is the point of futarchy.
